NPTEL Course on Principles of Compiler Design

Outline of the Lecture

- What is run-time support? (in part 1)
- Parameter passing methods (in part 1)
- Storage allocation (in part 2)
- Activation records (in part 2)
- Static scope and dynamic scope
- Passing functions as parameters
- Heap memory management
- Garbage Collection

Static Scope and Dynamic Scope

■ *Static Scope*

- ❑ A global identifier refers to the identifier with that name that is declared in the closest enclosing scope of the program text
- ❑ Uses the *static* (unchanging) relationship between blocks in the program text

■ *Dynamic Scope*

- ❑ A global identifier refers to the identifier with that name associated with the most recent activation record
 - ❑ Uses the actual sequence of calls that is executed in the *dynamic* (changing) execution of the program
- Both are identical as far as local variables are concerned

Static Scope and Dynamic Scope :

An Example

```
int x = 1, y = 0;
int g(int z)
{ return x+z;}
int f(int y) {
    int x; x = y+1;
    return g(y*x);
}
y = f(3);
```

x	1	outer block
y	0	

y	3	f(3)
x	4	

z	12	g(12)
----------	-----------	--------------

After the call to g,
Static scope: x = 1
Dynamic scope: x = 4

Stack of activation records
after the call to g

Static Scope and Dynamic Scope: Another Example

```
float r = 0.25;
void show() { printf("%f",r); }
void small() {
    float r = 0.125; show();
}
int main (){
    show(); small(); printf("\n");
    show(); small(); printf("\n");
}
```

- Under static scoping, the output is
0.25 0.25
0.25 0.25
- Under dynamic scoping, the output is
0.25 0.125
0.25 0.125

Implementing Dynamic Scope – Deep Access Method

- Use *dynamic link* as *static link*
- Search activation records on the stack to find the first AR containing the non-local name
- The depth of search depends on the input to the program and cannot be determined at compile time
- Needs some information on the identifiers to be maintained at runtime within the ARs
- Takes longer time to access globals, but no overhead when activations begin and end

Deep Access Method - Example

Stack of activation records

Global variable search direction

Base

Next

Calling sequence:
Main \rightarrow R \rightarrow Q \rightarrow R

Currently active procedure

Implementing Dynamic Scope – Shallow Access Method

- Allocate maximum static storage needed for *each* name (based on the types)
- When a new AR is created for a procedure *p*, a local name *n* in *p* takes over the static storage allocated to name *n*
 - Global variables are also accessed from the static storage
 - Temporaries are located in the AR
 - Therefore, all variable (not temp) accesses use static addresses
- The previous value of *n* held in static storage is saved in the AR of *p* and is restored when the activation of *p* ends
- Direct and quick access to globals, but some overhead is incurred when activations begin and end

Shallow Access Method - Example

Heap Memory Management

- Heap is used for allocating space for objects created at run time
 - For example: nodes of dynamic data structures such as linked lists and trees
- Dynamic memory allocation and deallocation based on the requirements of the program
 - *malloc()* and *free()* in C programs
 - *new()* and *delete()* in C++ programs
 - *new()* and garbage collection in Java programs
- Allocation and deallocation may be *completely manual* (C/C++), *semi-automatic* (Java), or *fully automatic* (Lisp)

Memory Manager

- Manages heap memory by implementing mechanisms for allocation and deallocation, both manual and automatic
- Goals
 - Space efficiency: minimize fragmentation
 - Program efficiency: take advantage of locality of objects in memory and make the program run faster
 - Low overhead: allocation and deallocation must be efficient
- Heap is maintained either as a doubly linked list or as bins of free memory chunks (more on this later)

Allocation and Deallocation

- In the beginning, the heap is one large and contiguous block of memory
- As allocation requests are satisfied, chunks are cut off from this block and given to the program
- As deallocations are made, chunks are returned to the heap and are free to be allocated again (*holes*)
- After a number of allocations and deallocations, memory becomes fragmented and is not contiguous
- Allocation from a fragmented heap may be made either in a *first-fit* or *best-fit* manner
- After a deallocation, we try to *coalesce* contiguous holes and make a bigger hole (free chunk)

First-Fit and Best-Fit Allocation Strategies

- The *first-fit* strategy picks the **first** available chunk that satisfies the allocation request
- The *best-fit* strategy searches and picks the smallest (**best**) possible chunk that satisfies the allocation request
- Both of them chop off a block of the required size from the chosen chunk, and return it to the program
- The rest of the chosen chunk remains in the heap

First-Fit and Best-Fit Allocation Strategies

- Best-fit strategy has been shown to reduce fragmentation in practice, better than first-fit strategy
- *Next-fit* strategy tries to allocate the object in the chunk that has been split recently
 - Tends to improve speed of allocation
 - Tends to improve spatial locality since objects allocated at about the same time tend to have similar reference patterns and life times (cache behaviour may be better)

Bin-based Heap

- Free space is organized into *bins* according to their sizes ([Lea Memory Manager in GCC](#))
 - ❑ Many more bins for smaller sizes, because there are many more small objects
 - ❑ A bin for every multiple of 8-byte chunks from 16 bytes to 512 bytes
 - ❑ Then approximately logarithmically (double previous size)
 - ❑ Within each “small size bin”, chunks are all of the same size
 - ❑ In others, they are ordered by size
 - ❑ The last chunk in the last bin is the *wilderness chunk*, which gets us a chunk by going to the operating system

Bin-based Heap – An Example

Ref: From Lea's
article on memory
manager in GCC

Managing and Coalescing Free Space

- Should coalesce adjacent chunks and reduce fragmentation
 - ❑ Many small chunks together cannot hold one large object
 - ❑ In the **Lea memory manager**, no coalescing in the exact size bins, only in the sorted bins
 - ❑ **Boundary tags** (free/used bit and chunk size) at each end of a chunk (for both used and free chunks)
 - ❑ *A doubly linked list of free chunks*

Boundary Tags and Doubly Linked List

3 adjacent chunks. Chunk B has been freed just now and returned to the free list. Chunks A and B can be merged, and this is done just before inserting it into the linked list. The merged chunk AB may have to be placed in a different bin.

Problems with Manual Deallocation

- Memory leaks
 - Failing to delete data that cannot be referenced
 - Important in long running or nonstop programs
- Dangling pointer dereferencing
 - Referencing deleted data
- Both are serious and hard to debug
- Solution: **automatic garbage collection**

Garbage Collection

- Reclamation of chunks of storage holding objects that can no longer be accessed by a program
- GC should be able to determine types of objects
 - Then, size and pointer fields of objects can be determined by the GC
 - Languages in which types of objects can be determined at compile time or run-time are type safe
 - Java is type safe
 - C and C++ are not type safe because they permit type casting, which creates new pointers
 - Thus, any memory location can be (theoretically) accessed at any time and hence cannot be considered inaccessible

Reachability of Objects

- The *root set* is all the data that can be accessed (reached) directly by a program without having to dereference any pointer
- Recursively, any object whose reference is stored in a field of a member of the root set is also reachable
- New objects are introduced through object allocations and add to the set of reachable objects
- Parameter passing and assignments can propagate reachability
- Assignments and ends of procedures can terminate reachability
